(54) INJECTION COMPRESSION MOLDING METHOD AND APPARATUS

(57) The present invention is an injection compression molding method and apparatus therefor capable of rapidly molding a multilayer molded product with high strength and high accuracy by a simple structure. A molding method for attaining such characteristics includes the steps of extending an injected molten resin (51) by compressing the same in metal molds (31, 32), opening the metal molds during or after the extension operation, injecting a surface layer material (60) into a gap (6) occurring between the metal molds (31, 32) and the resin (51) when the molds are opened, closing the molds during or after the injection of the surface layer material (60), and cooling the resin (51) and the surface layer material (60) in the closed metal molds (31, 32).

FIG. 1

EP 0 795 386 A1

Description

Technical Field

The present invention relates to an injection compression molding method and an apparatus therefore and particularly to an injection compression molding method and an apparatus therefor capable of rapidly molding a multilayer molded product with high strength and high accuracy by a simple structure.

Background Art

Many of the resin molded products are molded by using one kind of material, but some of them are multilayer molded products of the same material or different kinds of materials in order to obtain strength, or to add a special function such as, for example, electromagnetic wave shielding. It can be said that surface coating applied to a molded product is a kind of the above-described multilayer molded products. As for the conventional art for obtaining such multilayer molded products, the following can be cited.

There is an injection molding method in which a number of movable metal molds of different sizes are equipped for one fixed metal mold. In this method, the combinations of the metal molds are changed by successively changing a movable metal mold of small size to that of larger size for one fixed metal mold, and by laying resin of the same material or different materials at every time when the combination is changed, a multilayer product is obtained.

However, the entire structure becomes complicated by including a number of movable metal molds. The change of the movable metal molds can't be carried out until a molded product has been solidified to some extent by cooling resin, therefore the total time for molding becomes longer. In addition, synchronous programs for each motion of the movable metal mold and changing operation of the movable metal molds become complicated.

As for an art for surface coating, there are an art for coloring the surface of a finished molded product by a spray or a brush, an art for using colored resin for the top layer of a multilayer molded product molded based on the above-described conventional injection molding method, and an insert injection molding art for carrying out injection molding by previously providing a ready-made colored sheet inside the metal molds.

However, surface coating by a spray or the like requires a coating device or manpower, and compatibility (mutually soluble property) can't be secured on the boundary surface between coating material and a molded product unless special coating material is used, therefore adhering strength of coating material to a molded product and the bonding strength of the coating material itself become lower. The accuracy in coating such as coating thickness, coating flatness, or the like becomes lower. An insert injection molding art has an

advantage that various kinds of patterns and designs can adhere to the surface of a molded product, but unless the metal molds are heated, compatibility on the boundary surface between resin and a colored sheet can't be expected, therefore adhering strength of the colored sheet to a molded product is low.

As for another surface coating art, there is known an injection molding method in which metal molds are slightly opened after a cooling step is completed (specifically, a condition in which a gap occurs inside the metal molds by the shrinkage of a molded product), coating material is injected from a coating nozzle provided in the metal molds, the molds are closed again, and the coating material in the gap is dried (refer to, for example, Japanese Patent Application Laid-open No. 6-198672). This is an improved method of an injection molding method in which the amount of closing is not controlled, while in the injection compression molding method the amount of closing is freely controlled by a movable metal mold. Specifically, if the molds are closed after injecting coating material while resin is still hot by ordinary injection molding method, there is no gap between the metal molds and the molded product, so that the coating material has no place to go. Therefore, the coating material and the resin still in a liquid form leak to the outside of the metal molds, and poor molding is caused. The above-described improved method solves the disadvantage, and enables surface coating.

However, in the above-described improved injection molding method, the time of the completion of drying the coating material is delayed as much as the time required for the resin to be cooled. Since the gap into which the coating material is injected is basically determined not by the amount of closing but by the amount of shrinkage, the leakage from the metal molds to the outside occurs if an excessive amount of coating material is injected. On the other hand, if the amount of injection of coating material is too small, irregular coating will occur. When the thickness of a molded product is uneven, the amount of shrinkage differs at every uneven point, so that the amount of a gap caused by the shrinkage is varied, therefore irregular coating occurs. Further, since coating material is injected after the resin is cooled, compatibility on the boundary surface between the resin and the coating material can't be expected, therefore there is a disadvantage of lower adhering strength of coating material to a molded product and lower bonding strength of the coating material itself.

Disclosure of the Invention

The present invention is made to eliminate the disadvantages of the above-described conventional art, and its object is to provide an injection compression molding method and apparatus therefor capable of rapidly molding a multilayer molded product with high accuracy and high strength by a simple structure.

Explaining with reference to Fig. 1, an injection compression molding method relating to the present

invention is an injection compression molding method for obtaining a molded product by freely compressing molten resin injected into metal molds consisting of a movable metal mold and fixed metal mold in the metal molds, characterized by including the steps of.

- i) extending the molten resin by compressing the same in the metal molds (Step 101), and opening the metal molds during or after the extension operation (Step 102);
- ii) injecting a surface layer material into a gap occurring between the metal molds and the resin when the metal molds are opened (Step 103), and closing the metal molds during or after the injection of the surface layer material (Step 104); and
- iii) cooling the resin and the surface layer material in the closed metal molds (Step 105)

In the above-described structure, a molded product is obtained by freely compressing the molten resin injected into a cavity between the movable metal mold and a fixed metal mold in the movable metal mold and a fixed metal mold by moving the movable metal mold. According to the above-described invention of the method, the surface layer material is extended on the resin surface, while the resin in the metal molds is still hot. Accordingly, based on the following operation, a multilayer molded product can be taken out of the metal molds.

(1) Since surface layer material is extended while resin is still hot, the boundary surfaces of the resin and the surface layer material are integrally compatibilized, and the entire strength as a molded product is increased. When, for example, the surface layer material is coating material, the adhering strength of the coating material to a molded product and the bonding strength of the coating material itself are increased. In addition, since the resin is hot, the drying rate of the surface layer material such as coating material or the like is increased.

(2) Since surface layer material is extended on a hot surface of resin, evenness on the surface layer of the surface layer material can be maintained. Even if excessive amount of surface layer material is injected, poor molding such as the leakage of the surface layer material and molten resin to the outside or the like can be prevented from occurring by adjusting the amount of movement of the movable metal mold (incidentally, in an injection molding method, a movable metal mold can't be freely controlled like the above). For example, when the surface layer material is coating material, coating irregularity does not occur and the excellent appearance can be obtained.

An injection compression molding apparatus relating to the present invention is an injection compression molding apparatus equipped with metal molds consist-

ing of a movable metal mold and a fixed metal mold, for obtaining a molded product by freely compressing the molten resin injected into the metal molds in the metal molds, characterized by including.

- a surface layer material injecting means for injecting a surface layer material into a gap between the metal molds and the resin injected into the metal molds; and
- a control means for extending the resin by compressing the same in the metal molds, opening the metal molds during or after the extension operation, injecting the surface layer material from the surface layer material injecting means into the gap occurring between the metal molds and the resin when the metal molds are opened, closing the metal molds during or after the injection of the surface layer material, and cooling the resin and the surface layer material in the closed metal molds

In the above structure, the above-described invention of the method is memorized as an operation program, and besides the control means for controlling the operation, the surface layer material injecting means is included. By the present invention of the apparatus, for example, when a surface layer material and resin are of different materials, a multilayer (for example, two-layer) molded product can be obtained. The operation of the present invention of the apparatus conforms to the explanation of the above-described invention of the method.

Brief Description of the Drawings

Fig. 1 is a flow chart of an injection compression molding method relating to the present invention; Fig. 2 is a schematic block diagram of an injection compression molding apparatus relating to a first embodiment of the present invention;

Figs. 3A to 3H are schematic explanatory diagrams of a resin compressing section (metal molds) in a series of controlling steps relating to the first embodiment.

which the metal molds are stopped with the resin and the coating material being compressed and molded, and

Fig. 3H is an explanatory diagram of a condition in which the metal molds are opened to take out a molded product.

Best Mode for Carrying out the Invention

A preferable embodiment of an injection compression molding method and apparatus relating to the present invention will be particularly described with reference to the attached drawings in the below.

Fig. 2 is an example of an apparatus for coating a surface layer material (hereinafter referred to as a coating material 60) including filler metal for electromagnetic shielding on the surface of a molded product, and the apparatus is equipped with a resin injecting section 10, a coating material injecting means 20 forming a surface layer material injecting means, a resin compressing section 30, and a control means 40.

The resin injecting section 10 includes a screw cylinder 11, a hopper 12, and an on-off valve 13. The screw cylinder 11 is freely and directly moved by a direct acting actuator 42 and is freely rotated by a rotary actuator 43, and by synchronously operating these actuators 42 and 43, pellet-formed resin 50 supplied from the hopper 12 is mixed and melted. This molten resin 51 is injected from the on-off valve 13 into a cavity 33 inside metal molds 31 and 32 through the injection passage provided in the fixed metal mold 32.

The coating material injecting means 20 is defined by a tank 21, an injecting pump 22, and an on-off valve 23. The coating material 60 filled in the tank 21 is injected into the cavity 33 inside the metal molds 31 and 32 through the injecting pump 22, the on-off valve 23, and the injecting passage provided inside the fixed metal mold 32.

The resin compressing section 30 is defined by the movable metal mold 31 and the fixed metal mold 32. The movable metal mold 31 is freely and directly moved toward the fixed metal mold 32 by a direct acting actuator 44, and freely compresses and molds the resin 51, or the resin 51 and coating material 60 in the cavity 33 inside the metal molds 31 and 32.

The control means 40 is defined by a controller 41 consisting of a micro computer and so on, the actuators 42 to 44, the on-off valve 13, the injecting pump 22, and the on-off valve 23. Incidentally, the injection compression molding apparatus of the conventional art is also equipped with the controller for synchronously controlling the actuators 42 to 44 and the on-off valve 13, but the control means 40 of the embodiment is additionally equipped with synchronous control of the injecting pump 22 and the on-off valve 23 as compared to the conventional controller. The synchronous control of each of the actuators 42 to 44, the on-off valves 13 and 23, and the injecting pump 22 will be explained in the below with reference to Figs. 3A to 3H.

As Fig. 3A illustrates, in a condition in which the movable metal mold 31 is separated from (is away from) the fixed metal mold 32, the controller 41 sends a command to the direct acting actuator 44.

By this command, as Fig. 3B illustrates, the movable metal mold 31 is moved to the position where the molten resin 51 can be injected from the resin injecting section 10 to the fixed metal mold 32. After the completion of this movement, the controller 41 sends a command to the direct acting actuator 42, the rotary actuator 43, and the on-off valve 13. By this command, as Fig. 3C illustrates, a specified amount of molten resin 51 is injected into the cavity 33 inside the metal molds 31 and 32 from the injecting section 10. During the injection, or after the completion of the injection of the resin 51, the controller 41 sends a command to the direct acting actuator 44, and as Fig. 3D illustrates, the molten resin 51 is extended in the cavity 33 by moving the movable metal mold 31 further to the fixed metal mold 32.

During the above-described extension operation or after the completion of the extension operation, it is preferable that the controller 41 finds the timing when a skin layer (surface hardening layer) is formed on a molded resin surface of the molten resin 51 and sends a mold opening command to the direct acting actuator 44 to separate the movable metal mold 31 from the fixed metal mold 32 as far as a gap δ . In such a way, the molding resin 51 with a skin layer being formed on the surface is prevented from losing shape by the skin layer, though the molding resin 51 is still hot, and is separated from the fixed metal mold 32, adhering to the movable metal mold 31. By this separation, the gap δ is secured between the surface of the molding resin 51 and the fixed metal mold 32. Specifically, the gap δ is the total of a gap δ_1 between the surface of the molding resin 51 and the fixed metal mold 32 and a gap δ_2 between the back surface of the molding resin 51 and the movable metal mold 31 ($\delta = \delta_1 + \delta_2$).

Incidentally, the timing of the above-described mold opening command can be a time controlled by a timer from the time when the movable metal mold 31 is at a specified position (for example, the position where the extension operation is started). This mold opening command can be sent at a time when the movable metal mold 31 reaches a specified position (for example, the position previously determined by an experiment and so on, where a skin layer of a specified thickness is formed) based on the extending speed.

During the above-described separation or after the completion of the separation, the controller 41 sends a command to the injecting pump 22 and the on-off valve 23, and as Fig. 3F illustrates, the coating material 60 is injected into the gap δ from the coating material injecting means 20 (the injecting position corresponds to the above-described gap δ_1). During or after the injection of the coating material 60, the controller 41 sends a command to the direct acting actuator 44, and, as Fig. 3G illustrates, moves the movable metal mold 31 to the

fixed metal mold 32 again, then stops the movable metal mold 32 as compressing and molding the molding resin 51 and the coating material 60. At this time, the coating material 60 is extended to every corner of the inside of the gap δ 1. Incidentally, it is preferable that the injecting pressure of the coating material 60 is small pressure which does not break the skin layer.

The controller 41 finds the timing when the molten resin 51 and the surface layer material (coating material) 60 are cooled and solidified, or the timing when a problem does not occur to the molded product or on the surface thereof even if the molded product is taken out, and sends a command to the direct acting actuator 44. By this command, as Fig. 3H illustrates, the movable metal mold 31 is separated from the fixed metal mold 32, then the metal molds 31 and 32 are opened, and the coated molded product can be taken out.

The effect of the above-described first embodiment is as follows

- (1) The rate of drying the coating material 60 is large since the coating material 60 is extended on the surface of the resin 51 while the resin 51 inside the metal moldings 31 and 32 are still hot. In addition, since the coating material 60 is extended while the resin 51 is still hot, the molding resin 51 and the coating material 60 are integrally compatibilized on the boundary surface, and the adhering strength of the coating material 60 to the molding resin 51 is increased with the bonding strength of the coating material 60 itself being increased.
- (2) Even if an excessive amount of coating material 60 is injected, the amount of extension of the coating material 60 can be made uniform by adjusting the amount of movement of the movable metal mold 31, therefore there is no irregularity produced on coating and excellent appearance is maintained. If the coating material 60 including the above-described filler metal is used as a coating material in, for example, the above-described Japanese Patent Application Laid-open No. 6-198672, the filler metal prevents the flow, therefore the coating material 60 is difficult to be extended unless the amount of openings of the metal molds is increased. However, when the amount of the opening of the metal molds is increased, as pointed out in the disadvantages of the above-described Japanese Patent Application Laid-open No. 6-198672, an excessive amount of coating material 60 is injected, so that the leakage from the metal mold to the outside occurs, or irregularities are caused on coating. On the other hand, according to the present embodiment, there is no irregularity on coating and excellent appearance is obtained.

Then, the other embodiments will be explained.

In the first embodiment, the injection passage of the coating material 60 is only provided in the fixed metal mold 32, but the second embodiment is an example in

which an injection passage branching from the on-off valve 23 is further provided in the movable metal mold 31. The control of the second embodiment is basically the same as that of the first embodiment, but differs in a point that the coating material 60 is injected into the gaps δ 1 and δ 2.

The third embodiment is an example in which a number of surface layer material injecting means 20 are equipped. For example, in the case that two of the surface layer material injecting means 20 are equipped, one is a means for injecting liquefied resin including a large amount of electromagnetic wave shielding filler metal, and the other is a means just for injecting coating material. In this case, when explaining with reference to Fig. 2, the control is carried out as the following steps i) to v).

i) The molten resin 51 is extended by compressing the same in the metal molds 31 and 32, and the metal molds are opened during or after the extension operation,

ii) the above-described liquefied resin is injected into the gap δ occurring between the metal molds 31 and 32 and the resin 51 when the molds are opened, and during or after the injection of the resin, the metal molds are closed,

iii) the resin 51 and the liquefied resin are slightly cooled in the metal molds 31 and 32 as they are, and the metal molds are opened again,

iv) a simple coating material is injected into the gap δ occurring between the metal molds 31 and 32 when the molds are opened, and during or after the injection of the simple coating material, the molds are closed, and

v) the resin 51, liquefied resin and simple coating material are cooled in the metal molds 31 and 32 as they are

Specifically, the control is conducted in such a way as the steps iv) and v) is almost a repetition of the steps ii) and iii).

The fourth embodiment is a modified example of the steps of the third embodiment. The above-described embodiment is the ease of the surface layer being a thin layer, but a molded product sandwiching the resin including electromagnetic wave shielding filler metal between the resin 51 can be made. In this case, the control is carried out as follows.

i) The molten resin 51 is extended by compressing the same in the metal molds 31 and 32, and during or after the extension operation, the metal molds are opened,

ii) the liquefied resin including the above-described filler metal is injected into the gap δ occurring between the fixed metal mold 32 and the resin 51 when the molds are opened, and during or after the injection of the liquefied resin, the metal molds are closed.

iii) the resin 51 and the liquefied resin are slightly cooled in the metal molds 31 and 32 as they are, and the metal molds are opened again,

iv) the molten resin 51 is injected again into the gap δ occurring between the fixed metal mold 32 and the liquefied resin when the metal molds are opened, and during or after the injection of the resin 51, the metal molds are closed, and

v) the resin 51 and the liquefied resin are cooled in the metal molds 31 and 32 as they are.

Specifically, even when a number of resin injecting sections 10 for different materials are equipped, a molded product with excellent compatibility, which requires shorter producing time, can be obtained as in the first embodiment by carrying out the control of repeating the steps ii) and iii) as in the above

Industrial Applicability

The present invention is useful as an injection compression molding method and an apparatus therefor capable of rapidly obtaining a multilayer molded product of a high strength and high accuracy by a simple structure in which a surface layer material is extended on the surface of hot resin inside the metal molds

Claims

1. An injection compression molding method for obtaining a molded product by freely compressing molten resin injected into metal molds consisting of a movable metal mold and a fixed metal mold in said metal molds, comprising the steps of:
 - i) extending said resin (51) by compressing the same in said metal molds (31, 32), and during or after the extension operation, opening the metal molds;
 - ii) injecting a surface layer material (60) into a gap δ occurring between said metal molds (31, 32) and said resin (51) when the metal molds are opened, and during or after the injection of the surface layer material (60), closing the metal molds; and
 - iii) cooling said resin (51) and said surface layer material (60) in said closed metal molds (31, 32).
2. An injection compression molding apparatus equipped with metal molds consisting of a movable metal mold and a fixed metal mold, for obtaining a molded product by freely compressing molten resin injected into said metal molds in said metal molds, comprising:
 - a surface layer material injecting means (20) for injecting a surface layer material (60) into a gap δ between said metal molds (31, 32) and

said resin (51) injected into said metal molds (31, 32), and

a control means (40) for extending said resin (51) by compressing the same in said metal molds (31, 32), opening the metal molds during or after the extension operation, injecting said surface layer material (60) from said surface layer material injecting means (20) into the gap δ occurring between said metal molds (31, 32) and said resin (51) when the metal molds are opened, closing the metal molds during or after the injection of the surface layer material (60), and cooling said resin (51) and said surface layer material (60) in said closed metal molds (31, 32).
